Three call windows: primary-row reconciliation

The three event windows and their 24 same-weekday comparison windows were reconciled against the supplied March 3-June 1 PDF and May 31-July 24 CSV. All 10,585 row occurrences across the selected windows are checked by clock, normalized endpoints, call type and duration; the exact count is recorded in the accompanying reconciliation report.

A window is the two hours beginning at the exact email timestamp, with the end excluded. Comparison dates are the same weekday at the same clock time, one to four weeks before and after. City local-line labels are carried from the retained dataset; automated-only endpoints and self-calls are excluded. Only outgoing rows with both endpoints classified as City lines are included. Rows sharing a timestamp and endpoint pair form one group, using maximum recorded duration.

The original PDF is sorted by printed 12-hour time within dates, so morning and evening rows can interleave. Selection reads the entire source day before filtering by parsed Central time. CST/CDT labels are retained; clocks were not calibrated to an independent time standard.

April 7 and June 23 overlap other email windows. Same-weekday comparisons do not control for workload, holidays, seasonality or unrelated events. The counts do not establish participants, conversation content, coordination or causation. City numbers remain visible; no private outside-call rows are reproduced.
